

Dual Output Narrow Pitch Differential Speed and Direction Sensor IC

FEATURES AND BENEFITS

- Ideally suited for xEV asynchronous electric-motor applications with narrow-pitch targets
- High-speed switching bandwidth up to 40 kHz
- Two independent output channels with options for high-resolution XOR speed, pulse, and direction protocol
- ASIL-Compliant: ASIL B SEooC developed in accordance with ISO 26262, when used as specified in the safety manual
- Immune to common external magnetic disturbance
- EEPROM-enabled factory traceability throughout product lifecycle
- Also available without integrated magnet (see the A17502 datasheet)

PACKAGE:

4-Pin SIP
(suffix SG)

Not to scale

DESCRIPTION

The ATS17502 is a single IC solution designed for rotational position sensing of a ferrous gear target found in automotive and industrial electric-motor applications (often with specific application and safety requirements). The IC is housed in an SG package that incorporates a rare-earth magnetic pellet for ease of manufacturing, consistent application performance over temperature, and enhanced reliability.

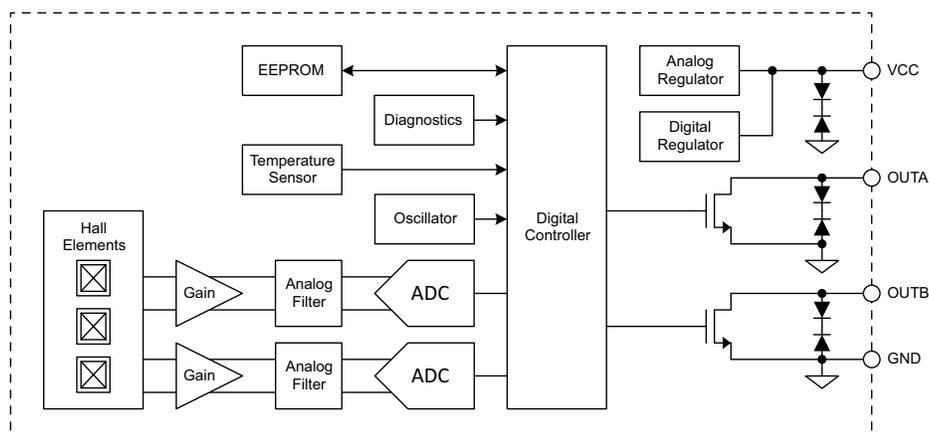

Three Hall elements are incorporated to create two independent differential channels. These inputs are processed by digital circuits and robust algorithms designed to eliminate the detrimental effects of magnetic and system offsets, and to address false output transitions caused by target vibrations in electric motors at startup and low-speed operation. The differential signals are used to produce a highly accurate speed output and, if desired, provide data about the direction of rotation.

Advanced calibration techniques are used to optimize signal offset and amplitude. This calibration, combined with digital tracking of the signal, results in accurate switch points over air gap, speed, and temperature.

The IC can be programmed for a variety of applications requiring dual-phase target speed and position signal data or simultaneous high-resolution target speed and direction data. It can be configured to enable fault-detection mode for ASIL B utilization. The ATS17502 was developed in accordance with ISO 26262 as a hardware safety element out of context (SEooC) with ASIL B capability for use in automotive safety-related systems when integrated and used in the manner prescribed in the applicable safety manual and datasheet.

The ATS17502 SG package is a lead (Pb) free 4-pin single inline package (SIP) with an integrated back-biasing magnet and a 100% matte-tin-plated lead frame.

[4] Typical values are for $V_{CC} = 5\text{ V}$ and $T_A = 25^\circ\text{C}$ unless otherwise specified.

[5] Maximum voltage must be adjusted for power dissipation and junction temperature; see representative for power derating discussions.

[6] Output characteristics are valid for each output independently, unless otherwise specified.

OPERATING CHARACTERISTICS (continued): Valid throughout operating ranges, unless otherwise specified

Characteristic	Symbol	Test Conditions	Min.	Typ. [7]	Max.	Unit	
OUTPUT CHARACTERISTICS (continued) [8]							
Fault Voltage [9]	V_{FAULT}	Fault-detection mode enabled; 5 V, 1 k Ω or 5 V, 3 k Ω option	High fault ($V_{\text{FAULT(HIGH)}}$)	4.5	–	–	V
			Mid fault ($V_{\text{FAULT(MID)}}$)	1.25	–	3.75	V
			Low fault ($V_{\text{FAULT(LOW)}}$)	–	–	0.5	V
		Fault-detection mode enabled; 12 V, 1 k Ω option	High fault ($V_{\text{FAULT(HIGH)}}$)	10.8	–	–	V
			Mid fault ($V_{\text{FAULT(MID)}}$)	3.6	–	8.4	V
			Low fault ($V_{\text{FAULT(LOW)}}$)	–	–	1.2	V
Allowable Pullup Voltage	V_{PULLUP}	Fault-detection mode disabled	4	–	24	V	
		Fault-detection mode enabled	5 V, 1 k Ω or 5 V, 3 k Ω option	4.75	–	5.25	V
			12 V, 1 k Ω option	11.4	–	12.6	V
Allowable Pullup Resistor [10]	R_{PULLUP}	Fault-detection mode disabled	–	1	–	k Ω	
		Fault-detection mode enabled	5 V, 1 k Ω option	0.8	–	1.46	k Ω
			5 V, 3 k Ω option	1.46	–	3.4	k Ω
			12 V, 1 k Ω option	0.9	–	1.1	k Ω
Allowable Load Capacitor [11]	C_{LOAD}	Fault-detection mode enabled	1	–	–	nF	
Output Leakage Current	$I_{\text{OUT(OFF)}}$	Fault-detection mode disabled; $V_{\text{OUT}} = V_{\text{OUT(HIGH)}}$	–	–	10	μA	
Duty Cycle	ΔD	Using reference target 90-0; $f_{\text{OP}} < 10$ kHz; wobble < 0.25 mm (maximum – minimum); -SD output protocol and algorithm selection	–	–	20	%	
Output Rise Time	t_r	10% \rightarrow 90%; $V_{\text{PULLUP}} = 5$ V; $R_{\text{PULLUP}} = 1$ k Ω ; $C_{\text{LOAD}} = 2.2$ nF	–	5	–	μs	
Output Fall Time	t_f	90% \rightarrow 10%; $V_{\text{PULLUP}} = 5$ V; $R_{\text{PULLUP}} = 1$ k Ω ; $C_{\text{LOAD}} = 2.2$ nF	Fault-detection mode disabled; Fast fall time option	–	0.5	–	μs
			Fault-detection mode disabled; Slow fall time option	–	3.5	–	μs
			Fault-detection mode enabled	–	6	–	μs
Forward Pulse Width [12]	$t_{\text{w(FWD)}}$	-P output protocol; Target features pass by sensor IC branded face pin 1 to pin 4	38	45	52	μs	
Reverse Pulse Width [12]	$t_{\text{w(REV)}}$	-P output protocol; Target features pass by sensor IC branded face pin 4 to pin 1	76	90	104	μs	
Propagation Delay	t_d	Delay from the magnetic signal crossing a switch point threshold to the start of the output transition	–	8	–	μs	

Continued on next page...

[7] Typical values are for $V_{\text{CC}} = 5$ V and $T_A = 25^\circ\text{C}$, unless otherwise specified.

[8] Output characteristics are valid for each output independently, unless otherwise specified.

[9] Valid with fault-detection mode enabled and correct programming of the fault-detection load-circuit option; see the Selection Guide.

[10] See the Typical Application Circuit section.

[11] Minimum capacitor required when fault-detection mode is enabled to ensure correct output levels over operating conditions. Increased load capacitance directly impacts maximum operating frequency due to the increased rise and fall times; see the Typical Application Circuit section.

[12] Time from start of output transition from $V_{\text{OUT(HIGH)}}$ to $V_{\text{OUT(LOW)}}$ to end of output transition from $V_{\text{OUT(LOW)}}$ to $V_{\text{OUT(HIGH)}}$. Measured pulse width varies with load-circuit configurations and measurement thresholds. Valid with pulse or pulse inverted output protocol; see the Programming Options section.

OPERATING CHARACTERISTICS (continued): Valid over operating ranges, unless otherwise specified

Characteristic	Symbol	Test Conditions	Min.	Typ. [14]	Max.	Unit	
SWITCH POINT CHARACTERISTICS							
Operate Point	B_{OP}	% of $B_{DIFF(pk-pk)}$; $V_{OUT} = V_{OUT(LOW)} \rightarrow V_{OUT} = V_{OUT(HIGH)}$; -D algorithm selection	-	70	-	%	
Release Point	B_{RP}	% of $B_{DIFF(pk-pk)}$; $V_{OUT} = V_{OUT(HIGH)} \rightarrow V_{OUT} = V_{OUT(LOW)}$; -D algorithm selection	-	30	-	%	
Hysteresis	B_{HYS}	ΔB_{DIFF} after switch point to allow next output transition	% of $B_{DIFF(pk-pk)}$; -D algorithm selection	-	40	-	%
			-Q algorithm selection	-	10	-	G
INPUT CHARACTERISTICS							
Operating Frequency	f_{OP}	Fundamental frequency of the input magnetic signal	-S output protocol	0	-	40	kHz
			-V or -W output protocol	0	-	20	kHz
Forward Pulse Operating Frequency	$f_{OP(FWD)}$	-P output protocol	0	-	9	kHz	
Reverse Pulse Operating Frequency	$f_{OP(REV)}$	-P output protocol	0	-	6	kHz	
Operating Magnetic Input Signal Variation [16]	$\Delta B_{DIFF(pk-pk)}$	Bounded amplitude ratio within T_{WINDOW} ; no missed output transitions; possible incorrect direction data and/or reduction in switch-point accuracy; see Figure 3 and Figure 4	0.6	-	2	-	
Operating Magnetic Input Signal Variation Window	T_{WINDOW}	Rolling window in which $\Delta B_{DIFF(pk-pk)}$ cannot exceed bounded ratio; see Figure 3 and Figure 4	8	-	-	T_{CYCLE}	
Operating Air Gap [15]	AG	Using reference target 90-0; $f_{OP} < 10$ kHz; -D algorithm selection	Fault-detection mode disabled	0.5	-	2	mm
			Fault-detection mode enabled	0.5	-	1.75	mm
THERMAL CHARACTERISTICS							
Package Thermal Resistance	$R_{\theta JA}$	Minimum-K PCB, single-layer, single-sided, with copper limited to solder pads	-	126	-	$^{\circ}C/W$	
		Low-K PCB, single-layer, single-sided, with copper limited to solder pads and 3.57 in ² (23.03 cm ²) of copper area each side	-	84	-	$^{\circ}C/W$	

[14] Typical values are for $V_{CC} = 5$ V and $T_A = 25^{\circ}C$, unless otherwise specified.

[15] Operating air gap is dependent on the available magnetic field. The available magnetic field is target geometry, material, and speed dependent. Operation air gap should be independently characterized for each target.

FUNCTIONAL DESCRIPTION

General

The ATS17502 sensor module contains a single-chip, dual differential Hall-effect sensor IC, a rare-earth pellet, and a flat ferrous pole piece (concentrator). As shown in Figure 6, the Hall-effect sensor IC supports three Hall elements that sense the magnetic profile of the ferrous gear target simultaneously but at different points (each channel spaced at 1.1 mm pitch), generating two differential internal signals processed for precise switching of the digital output signals. Direction of rotation can be determined based on the phase relationship of the two differential internal signals. The ATS17502 is intended for use with ferromagnetic targets.

The Hall-effect sensor IC is self-calibrating and possesses a temperature-compensated amplifier as well as a full-range analog-to-digital converter (ADC). This allows for accurate processing of a wide range of target magnetic-profile amplitudes and offsets. The on-chip voltage regulator provides supply-noise rejection throughout the operating voltage range. Changes in temperature do not greatly affect the ATS17502 due to the stable amplifier design and full-range ADC. The Hall elements and signal-processing electronics are integrated on the same silicon substrate.

The ATS17502 is capable of providing digital data representative of the mechanical features of a rotating target gear. The automatic translation of the mechanical profile to the digital output signal is shown in Figure 6. Additional optimization is not needed, and minimal processing circuitry is required. This ease of use reduces design time and incremental assembly costs for most applications.

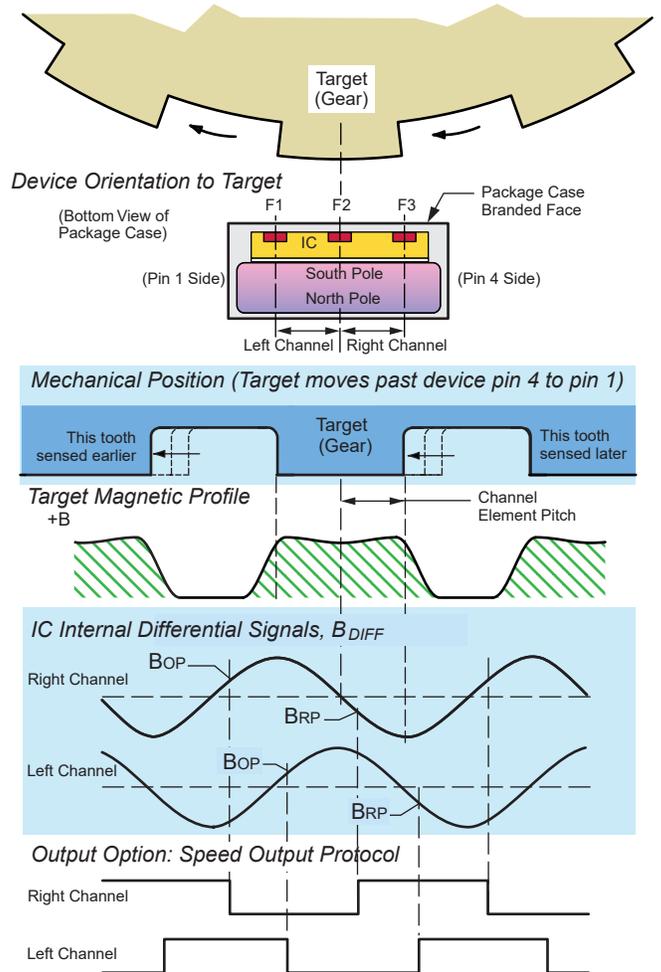

Figure 6: Magnetic Profile and Switch Points
($B_{OP} = 70\%$, $B_{RP} = 30\%$)

Threshold Algorithm

The ATS17502 contains selectable algorithms for determining when to produce an output transition from the magnetic input signal. For all options, a threshold is set within the sensor IC that triggers the output transition when crossed by the digitized magnetic signals (switch point).

Dynamic Threshold

With the ATS17502 programmed for the dynamic threshold option, each switch point is calculated from data obtained from the previous target feature. This algorithm allows for robust tracking to produce accurate output transitions for inconsistent magnetic input signals (offset drift, amplitude changes, etc.).

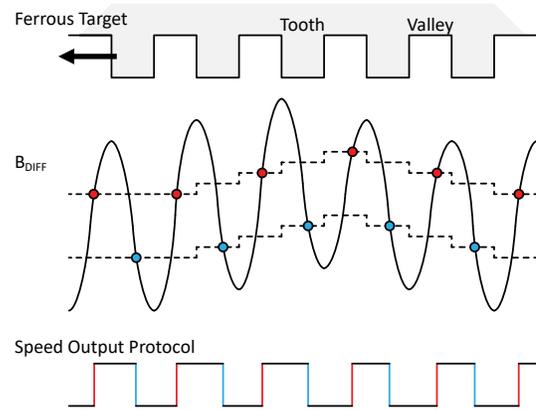

After power-on, the magnetic input signal is tracked to find the peaks of the signal. After each new peak is found, the switch points are updated based on a percentage of the previous two peaks.

Fixed Threshold

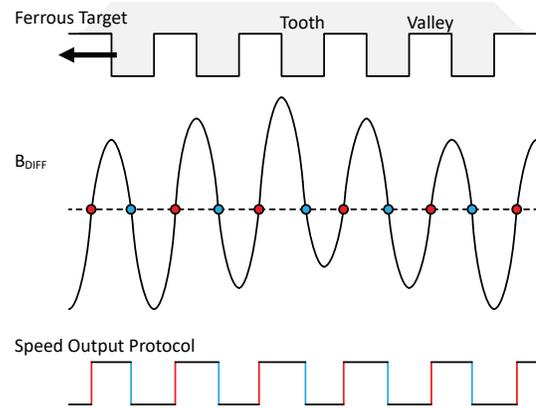

With the ATS17502 programmed for the fixed threshold option, an absolute threshold stored in memory is used to set the switch point for both the operate point and the release point. This algorithm allows for accurate output transitions immediately after power-on for consistent magnetic input signals without the need to “learn” the signal. The threshold stored in memory and loaded during power-on contains threshold levels over temperature to allow for offset drift adjustment of the magnetic input signal over temperature. The ATS17502 sensor IC contains a temperature sensor used continuously to adjust the switch point over temperature as needed by the application.

The fixed thresholds stored in memory can be preprogrammed for unique switch points over temperature for each application. Additionally, the ATS17502 can find and set the threshold for each installation over temperature during end-of-line calibration.

If, during the application, the magnetic input signal offset does not match the programmed threshold stored in memory (due to inaccurate programming, mechanical shift, etc.), the ATS17502 identifies the threshold as out of range, calculates the threshold for the current temperature, and updates the threshold to produce correct output transitions. After the update, algorithms use the current temperature to recharacterize the threshold over the operational temperature range. This prevents the update from overcompensating the threshold at a distant temperature relative to the update temperature. After the updated threshold is confirmed to be within the magnetic input signal’s switch point range over several target features, the updated threshold is stored into memory such that it can be used for subsequent power-on cycles.

**Figure 7: Dynamic Threshold Option
Switch Point Algorithm ($B_{OP} = 70\%$, $B_{RP} = 30\%$)**

**Figure 8: Fixed Threshold Option
Switch Point Algorithm**

Hybrid Threshold

With the ATS17502 programmed for the hybrid threshold option, the threshold is determined from the fixed threshold option at startup, then transitions to the dynamic threshold option after tracking signals have correctly acquired the magnetic input signals. This algorithm allows for both accurate output transitions immediately following power-on for consistent magnetic input signals as well as robust tracking to produce accurate output transitions of inconsistent magnetic input signals (offset drift, amplitude changes, etc.).

Once the tracking signals have identified consistent peak values from the magnetic input signal, the algorithm transitions from

using the fixed threshold switch point to using the dynamic threshold switch points. This transition occurs only when the magnetic input signal is near a maximum or minimum value, such that double-switching on the transition can be avoided.

While the majority of the power-on uses the dynamic threshold option for robust signal tracking, the ATS17502 continues to monitor the fixed threshold for comparison to the fixed threshold stored in memory. Should the fixed threshold require an update, the ATS17502 updates and writes the new threshold to memory for use in subsequent power-on cycles.

Output

Output Protocol

The ATS17502 contains several selectable options to change the output protocol or adjust the output behavior. These options allow for the ATS17502 to be programmed to application-level needs; see Figure 9. If the datasheet output protocol options are not quite fit for the application, consult Allegro MicroSystems about custom sensor programmability.

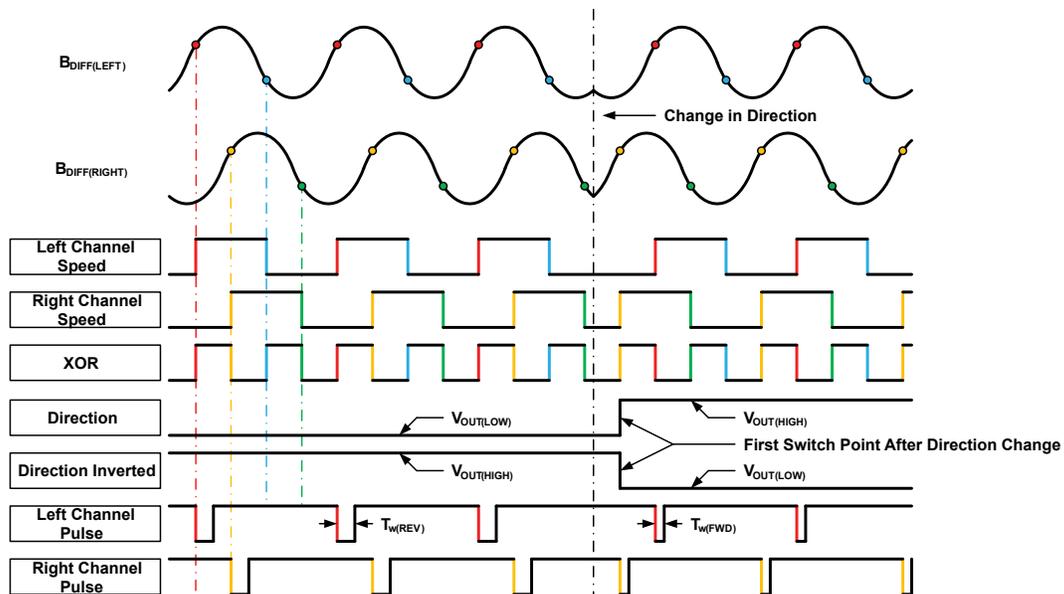

Figure 9: Output-Protocol Options

Fault-Detection Mode

The ATS17502 allows for the output to transition between one of two sets of values. With fault-detection mode disabled, the output transitions between approximately 0% and 100% of V_{PULLUP} ; see Figure 10. With fault-detection mode enabled, the output transitions between approximately 20% and 80% of V_{PULLUP} ; see Figure 10.

At the beginning of power-on, the ATS17502 outputs initialize to the V_{PULLUP} level. With fault-detection mode enabled, the output levels transition from V_{PULLUP} to V_{HIGH} before the end of power-on. After power-on, the output transitions as determined by the programmed algorithm and output protocol between $V_{OUT(HIGH)}$ and $V_{OUT(LOW)}$.

Enabling fault-detection mode allows for additional communication for cases of open wire or short circuit, as well as allowing for the ATS17502 to communicate a fault detected from the internal diagnostics. For a typical application load circuit, these cases can be detected by observing either OUTA or OUTB transition to approximately 0 V or V_{PULLUP} after t_{PO} .

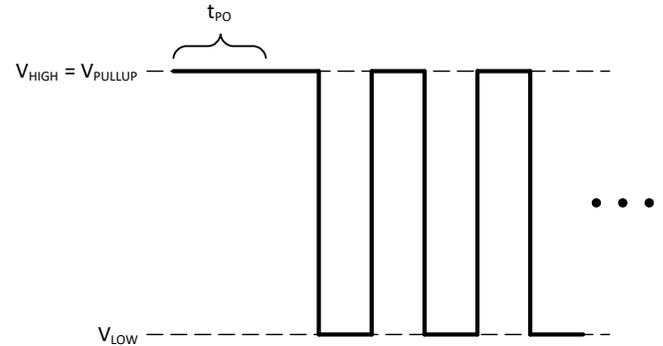

Figure 10: Fault-Detection Mode Disabled Output

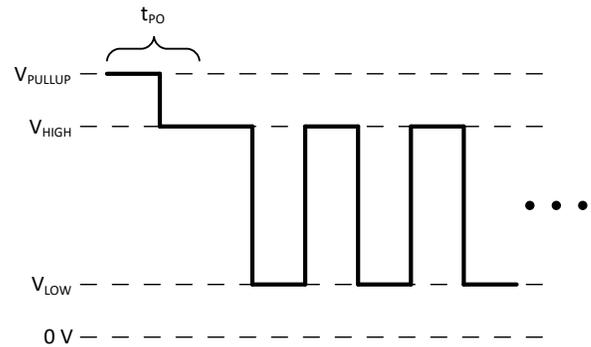

Figure 11: Fault-Detection Mode Enabled Output

Fault Voltage

The ATS17502 communicates a fault condition by configuring either output to hold within one of three V_{FAULT} ranges (high, mid, and low) for greater than 1 millisecond. Typical operation allows for output transitions to occur over the $V_{\text{FAULT(MID)}}$ range; as such, it is necessary to ignore fast transients for less than 1 millisecond through this range.

For internal diagnostics that trigger fault conditions (force the output to go to V_{FAULT}), both outputs transition to the $V_{\text{FAULT(HIGH)}}$ range. Because there may exist internal or external faults that cause either or both output pins to hold a $V_{\text{FAULT(MID)}}$ or $V_{\text{FAULT(LOW)}}$ level, these fault ranges should also be monitored. Examples of these fault conditions could be a short circuit of the output to ground, forcing the output to $V_{\text{FAULT(LOW)}}$, or a fault in the IC output controller that forces the output to $V_{\text{FAULT(MID)}}$.

For examples of the output communicating a fault condition, see Figure 12, Figure 13, and Figure 14.

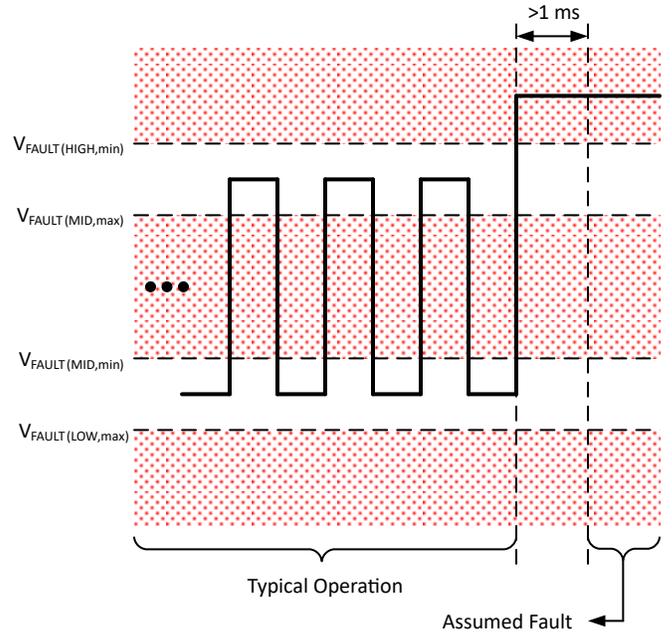

Figure 12: Assumed Fault Example: High Fault

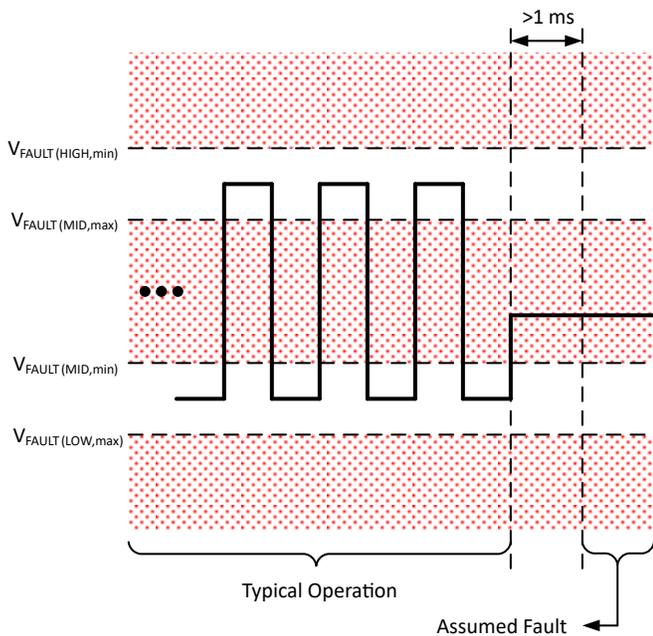

Figure 13: Assumed Fault Example: Mid Fault

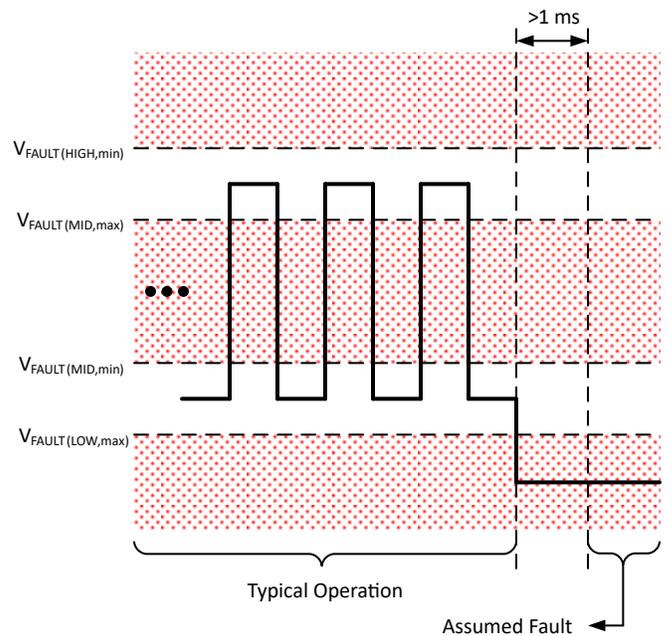

Figure 14: Assumed Fault Example: Low Fault

DEVICE FEATURES

Undervoltage Lockout

When supply voltage reduces to less than the undervoltage lockout voltage ($V_{CC(UV)}$), the ATS17502 enters reset, where the output state returns to the power-on state (POS) until sufficient V_{CC} is supplied. This feature prevents false signals, caused by undervoltage conditions, from propagating to the output of the sensor IC.

Power-Supply Protection

The ATS17502 contains an on-chip regulator and can operate over a wide V_{CC} range. For applications that need to operate from an unregulated power supply, transient protection must be added externally. For applications using a regulated line, electro-magnetic interference (EMI)/radio-frequency interference (RFI) protection is recommended. For more information about circuitry to address electromagnetic-compatibility (EMC) requirement compliance, contact Allegro. Refer to the Typical Application Circuit section.

Startup Hysteresis

With a power-on and a target held at zero-speed ($f_{OP} \approx 0$ Hz), noise and/or vibration can produce magnetic input signals. Startup hysteresis prevents peak-tracking and switch-point setting at startup immediately following power-on. This occurs until the sensed differential magnetic signal has moved sufficiently to satisfy the hysteresis band for signal tracking. This feature helps to ensure optimal self-calibration of the magnetic signals by rejecting electrical noise and low-amplitude target vibrations during startup and ensures that calibration occurs on actual target features.

Small-Signal Lockout

When $B_{DIFF(pk-pk)}$ reduces to less than the specification, the internal logic of the sensor IC indicates a reduced signal, as measured in an excessive air gap or a vibration condition. Small-signal lockout holds the output state at the level when $B_{DIFF(pk-pk)}$ was last in-specification. Once $B_{DIFF(pk-pk)}$ returns to an in-specification value, the output state is released to transition as expected during typical operation. When direction data is not explicitly defined by the selected output protocol, small-signal lockout is controlled independently for each channel. For example, left-channel speed + right-channel speed output protocol allows for one channel to continue switching while the other is in lockout.

When direction data is explicitly communicated, for example XOR + direction output protocol, small-signal lockout occurs when the $B_{DIFF(pk-pk)}$ of either channel reduces to less than the specification.

Vibration-Robust Signal Tracking

During vibration events, the magnetic input signals can produce oscillations with a sufficient amplitude for the peak-tracking algorithms to bound in and produce a nonideal peak-to-peak. When the ATS17502 detects a direction change, inward bounding of the peak-tracking signals is prevented. This prevents cases of erroneous output transitions from switch points being incorrectly set from vibration signals. Additionally, this allows for immediate acquisition of the magnetic input signals once real target rotation resumes following a vibration event.

Signature-Region-Robust Signal Tracking

Signature teeth (characterized by an extra target tooth and/or valley) can produce significant variations of the magnetic input signals. The bounded updating of the tracking signals prevents overcompensation for these signature variations to provide robust and accurate switch points for the signature region, as well as the features about the signature region.

Temperature-Drift-Robust Signal Tracking

Because temperature changes can impact both the amplitude and offset of the magnetic signal, a full-range ADC, advanced algorithms, temperature compensation, watchdog timers, and an internal temperature sensor ensure robust signal tracking over temperature.

To compensate for amplitude changes over temperature, temperature-compensated gain is first applied to normalize the amplitude over temperature. The full-range ADC and peak-tracking algorithms track and acquire the signal to accurately set the switch points.

To compensate for offset changes over temperature, a unique algorithm is implemented to ensure the signal tracking accurately follows and updates the switch points over offset drift. With no target rotation (stopped condition), a watchdog timer is implemented, which adjusts the peaks to track together, allowing for preservation of the correct signal peak-to-peak and switch points once rotation resumes.

Diagnostics and Fault Reporting

The ATS17502 contains diagnostics monitors of analog and digital circuits of the IC. These continuously monitor and report if any defect, calculation error, or invalid input stimulus is found. If a diagnostic monitor activates, the outputs of the ATS17502 transition to a V_{FAULT} level. For all faults, the outputs remain at the V_{FAULT} level for enough time to allow the system controller to monitor that a fault has occurred. For some diagnostics, it is possible to clear the fault with a reset of the internal controller of the sensor IC. If any of those diagnostic monitors triggers the fault event, the ATS17502 automatically performs a reset of the internal controller after the output is held at V_{FAULT} for enough time to allow the system controller to monitor the fault event.

For diagnostics and fault reporting to perform correctly, the user must ensure proper programming and must adhere to the specifications and assumptions stated in this datasheet, the ATS17502 Safety Manual, and any other addendum, corrigendum, and application note that applies to the ATS17502. For more information about diagnostics and fault reporting, see the ATS17502 Safety Manual.

Recalibration

Under large amplitude vibration conditions at startup, the peak-to-peak and phase relationship of the magnetic input signals can meet the conditions to calibrate. Once typical rotation resumes, the actual signal amplitudes can be much larger than the peak signals acquired during calibration. Rather than wait several T_{CYCLE} events for the peak signal to be tracked to actual levels, the ATS17502 detects the difference and recalibrates to the new signal. Recalibration allows for fast and robust correction from cases of calibration on vibration events.

Pulse-Collision Prevention

In cases of high-speed vibration, output transitions can occur at very high frequencies. To prevent pulse collision (truncation of the pulse width), the ATS17502 prevents output transitions until the current output-pulse transition is complete. This ensures the system controller can accurately interpret the output signal. This feature is only implemented when a pulse protocol option is selected.

High Configurability

The ATS17502 contains programmable parameters, as shown in the Selection Guide, that can be configured to provide application-level optimization.

POWER DERATING

The device must be operated at less than the maximum junction temperature of the device ($T_{J(max)}$). Under certain combinations of peak conditions, reliable operation may require derating supplied power or improving the heat dissipation properties of the application. This section presents a procedure for correlating factors affecting operating T_J . (Thermal data is also available on the Allegro MicroSystems website.)

The package thermal resistance ($R_{\theta JA}$) is a figure of merit summarizing the ability of the application and the device to dissipate heat from the junction (die), through all paths to the ambient air. Its primary component is the effective thermal conductivity (K) of the printed circuit board, including adjacent devices and traces. Radiation from the die through the device case ($R_{\theta JC}$) is a relatively small component of $R_{\theta JA}$. Ambient air temperature (T_A) and air motion are significant external factors, damped by overmolding.

The effect of varying power levels (power dissipation or P_D), can be estimated. The following formulas represent the fundamental relationships used to estimate T_J , at P_D :

Equation 1: $P_D = V_{IN} \times I_{IN}$

Equation 2: $\Delta T = P_D \times R_{\theta JA}$

Equation 3: $T_J = T_A + \Delta T$

For example, given common conditions, such as: $T_A = 25^\circ C$, $V_{CC} = 12 V$, $I_{CC(avg)} = 8.5 mA$, and $R_{\theta JA} = 126^\circ C/W$, then:

$$P_D = V_{CC} \times I_{CC(avg)} = 12 V \times 8.5 mA = 102 mW$$

$$\Delta T = P_D \times R_{\theta JA} = 102 mW \times 126^\circ C/W = 12.9^\circ C$$

$$T_J = T_A + \Delta T = 25^\circ C + 12.9^\circ C = 37.9^\circ C$$

A worst-case estimate, $P_{D(max)}$, represents the maximum allowable power level ($V_{CC(max)}$, $I_{CC(max)}$), without exceeding $T_{J(max)}$, at a selected $R_{\theta JA}$ and T_A .

For example, calculating reliability of V_{CC} given observed worst-case ratings, specifically:

$$T_A = 160^\circ C, R_{\theta JA} = 126^\circ C/W, T_{J(max)} = 175^\circ C, V_{CC(max)} = 24 V, \text{ and } I_{CC(max)} = 15 mA.$$

The maximum allowable power, $P_{D(max)}$, can be calculated by first inverting Equation 3 and calculating the maximum allowable increase to T_J :

$$\Delta T_{max} = T_{J(max)} - T_A = 175^\circ C - 160^\circ C = 15^\circ C$$

Then, maximum allowable power can be calculated by:

$$P_{D(max)} = \Delta T_{max} \div R_{\theta JA} = 15^\circ C \div 126^\circ C/W = 119 mW$$

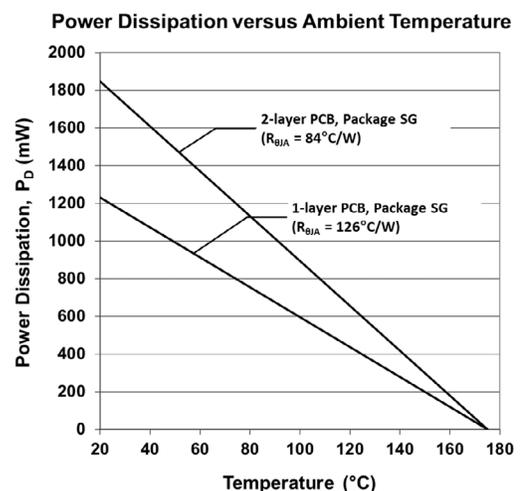

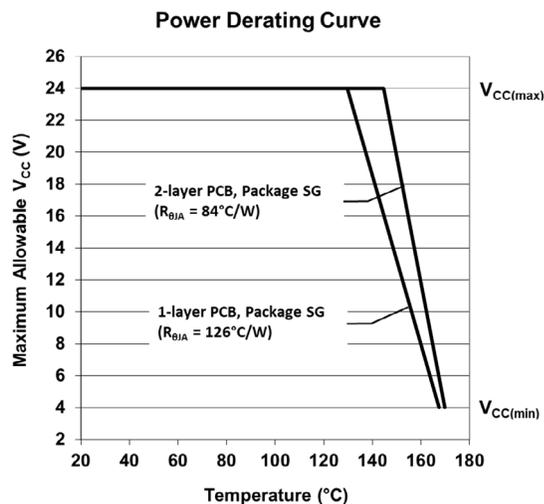

Finally, invert Equation 1 with respect to voltage:

$$V_{CC(est)} = P_{D(max)} \div I_{CC(max)} = 119 mW \div 15 mA = 7.9 V$$

The results indicate that, at T_A , the application and ATS17502 can dissipate adequate amounts of heat at voltages less than or equal to $V_{CC(est)}$.

Compare $V_{CC(est)}$ to $V_{CC(max)}$:

- If $V_{CC(est)} \leq V_{CC(max)}$, reliable operation between $V_{CC(est)}$ and $V_{CC(max)}$ requires enhanced $R_{\theta JA}$.
- If $V_{CC(est)} \geq V_{CC(max)}$, operation between $V_{CC(est)}$ and $V_{CC(max)}$ is reliable under these conditions.

Revision History

Number	Date	Description
–	January 5, 2023	Initial release
1	March 8, 2023	Updated Output Characteristics (page 6)
2	August 25, 2023	Updated part numbering schematic (page 2), Reverse Supply Current maximum value (page 5), Output Sink Current notes (page 3), First Output Edge and Initial Calibration test conditions (page 5), footnote 4 (page 5), Duty Cycle, Forward Pulse Width and Reverse Pulse Width test conditions (page 6); removed Jitter and footnote 13 (page 6); updated footnotes 7 and 12 (page 6), Operate Point, Release Point, and Hysteresis test conditions, Operating Frequency, Forward and Reverse Pulse Operating Frequency test conditions (page 7); removed Operating Magnetic Input and Operating Magnetic Peak (page 7); updated Operating Air Gap and footnote 14 (page 7); removed footnotes 15 and 16 (page 7); updated Characterization plots (page 11), Output section (page 15), and Figure 11, Figure 12, and Figure 13 (page 17).
3	April 10, 2024	Updated ASIL status (pages 1), updated calibration characteristics (page 5), and made minor editorial corrections throughout, including changing the future tense (“will”) to the present tense where appropriate, updating archaic language (“normal” changed to “typical”), adding missing hyperlinks to cross-references, and minimizing use of capitalization.
	April 23, 2025	Changed ASIL logos and ASIL description for clarity (page 1); updated algorithm selection options (page 2); removed typical values from allowable pullup voltage characteristic (page 6); updated test conditions for operate point, release point, hysteresis, and operating air gap (page 7); added fixed threshold and hybrid threshold descriptions (pages 13 – 14); and made minor editorial changes throughout.
